## ABSTRACT

The design of a microprocessor command language, RSCL, is discussed. RSCL provides the capability of building variable shell environments on a standard microprocessor system. These environments present a menu driven, screen oriented user interface as opposed to the line oriented interface of current operating systems.

The RSCL is a straightforward, easily understandable and complete computer programming language. Designed according to specific command language guidelines, it allows the user to make maximum utility of his skills.

A prototype implementation and sample program runs are included. These illustrate the design features and serve as a test platform for future research.

## ACKNOWLEDGMENTS

The authors wish to thank the following people. LCDR Ron Modes, our advisor, for supplying the necessary guidance and support to see us through the difficult times. Prof Dan Davis, our second reader, for his insight into future trends in user friendly systems. Mr. Al Wong for his assistance in debugging our 'C' interpreter. Finally, and most importantly, to our wives, Dawn and Royan, and our children Dennis and Annie and Stacy, Suzanne, Shelly and Scott for supporting the successful completion of our work.

## TRADEMARKS

## I. INTRODUCTION

### A. BACKGROUND

In the early days of computing it was simply man against the primitive operations of the computer. There was no need for any Command language because programming was done bit by bit without complex interfacing. Computer systems consisted of many tubes, a few cable connections, and possibly a peripheral device to display the results (output). The programmers of the early days were considered jack of all trades. They designed the rudimentary programs, entered them bit by bit by re-arranging the cable configurations and should problems arise they were the only trained maintenance technicians. This idyllic situation did not persist for long.

Advances in computer technology especially in regards to resources available made it imperative that the user be given some access mechanism to these resources. The first system to provide such a means was the IBM 360. The system required precise instructions to execute the system functions. Unfortunately, these instructions were not self generated like today's systems but required external media intervention. This external media was in the form of punch cards each containing a precise coded instruction which was then feed into the system along with the program card deck. The system designers either misconceived the effect of these cards on programmers or miscalculated their abilities to achieve an automated system. The result was catastrophic. The first of the Command languages was a piece meal language conceived in part as an after thought to a poor system design. The IBM language called a JCL (Job Control Language) did just that, it controlled the program execution by the

insertion of instruction cards throughout the program to manage the system's resources. The language was ambiguous, inconsistent, machine dependent and designed with little concern for the user. The impact of the IBM JCL language spawned numerous research efforts several of which are outlined.

During the late 1960's and early 1970's several organizations established working groups to study the JCL and OSCL (Operating System Control Language) interface problem. The first organization to study the problem was the American Standards Institute Committee on Programming Languages (ANSI) in June of 1967 [Ref. 1]. They conducted extensive surveys of nine existing O/S systems and their control languages. Their findings concluded with a list of five recommendations

- 
1. The need for a standard OSCL exists and its attainment is possible
  2. Several features now present in O/S should not be included in the standard
  3. None of the existing OSCL's surveyed are suitable as candidates for a standard language
  4. There should only be a single standard OSCL
  5. Piecemeal standardization should be avoided

**Figure 1.1 ANSI OSCL Study Recommendations.**

for a design proposal, figure 1.1

The Dutch established committees in September of 1971 and conducted numerous meetings under the auspices of the Netherlands Centre for Informatics. They focused on the basic functions of job control as related to data processing and job control inputs. The committee developed a list of basic job control functions, Figure 1.2, is a synopsis of their classification of related O/S functions.

1. Allocation (of resources)
2. Conditional Selection (of part of a job)
3. Execution (of a computer program)
4. Declaration (of job attributes)

Figure 1.2 Dutch JCL Committee's Basic Job Functions.

In late 1972 the CODASYL (Conference on Data System Languages) organization conducted follow on studies to the ANSI research. They determined that the ANSI committee had only addressed the feasibility aspect of a standardized language and so set out to design a standard OSCL language. Three working goals were established to guide the research: investigate the functional requirements for communications between the user, the functional program and the hardware; determine the functions necessary to define a standard OSCL language and what problems such a language would have on an O/S; develop linguistic elements which possess these functions and define a machine-independent OSCL.

Since these early studies other organizations i.e. US Federal Information Processing Standards (FIPS), IEEE, ACM, British Computer Society, US Department of Defense (DOD), etc. both government and privately sponsored have contributed to the research and development of several prototype OSCL languages.

The problem of standardizing Command Languages has perpetuated itself over the years. To date only a few languages (systems) merit any consideration as possible solutions.

## B. PURPOSE

The purpose of this project was to design a system which will enable the user to easily define a screen oriented environment (shell) for interfacing to microprocessor based computer systems.

The shell provides an abstract view of the computer system to the user. Through it command access can be controlled and a standard JCL can be created which will operate on multiple computers and operating systems. In this way, any computer system can be tailored to perform exactly as desired for each command. In addition, the same commands can be made to execute in exactly the same manner regardless of the resident operating system. This can have substantial cost saving effects in locations where multiple computers are used. Personnel will not have to be trained for each system since all systems will operate with the same JCL.

## C. SCOPE

Chapter two discusses the issues involved in the design of a command language. Guidelines for the design are also presented. The features of the command language are described in Chapter three. Chapter four discusses the factors which were involved in the design. The assumptions made, the criteria established and the decisions based on them are listed. A prototype implementation is described in Chapter five. The operation of the system from the point of view of a user creating a shell environment with the command language is discussed in Chapter six. Our conclusions and recommendations including the results of the prototype implementation are presented in Chapter seven. Appendices A, B and C include the RSCL grammar, a User's Manual for the RSCL and a CLI program source code listing of the prototype implementation, respectively.

## II. COMMAND LANGUAGE ISSUES

### A. DESIGN ISSUES

Four design issues confront the designers of any interactive Command language [Ref. 2]. First, how many modes of operation should the user be forced to learn. Second, the selection sequence of commands should be consistent and not change with varying machine implementation schemes. Third, an abort mechanism must be provided to the user to terminate a command sequence without losing the current scope or environment. Finally, a clear and concise error message system must be provided to quickly resolve syntactic and semantic problems. These design issues are not all inclusive and further issues will be brought forward as the need arises.

#### 1. COMMUNICATION STYLES

Many CL (command language) communication styles are available today. Direct keyboard entry, using pre-defined commands, allows the user to directly control the machine operations, but requires the user to learn a new, possibly cryptic, language for each OS/machine used. Another method uses keyboard response dialogue to screen prompts. This method is easier to use, but requires modification of the prompts whenever a change in functions is made. Function keys are a third method for users to communicate with the system. They are very fast and simple to use. The drawback with this method is some machines do not provide a function key option or an easy means to redefine the existing key functions. The last communication style to be mentioned is the screen menu format. This style is seen as the way of the future. Commands and data are displayed on the screen

in menu form. The user references the command/data by positioning the cursor at the desired field or by marking the position with a light pen. Data changed on the screen are correspondingly changed in the data base. Criptic one-line commands to the O.S. are no longer required.

Some systems (Xerox Smalltalk) provide a controlled pointer (mouse) to indicate which function is to be invoked. The Apple Lisa system uses the position of the cursor to highlight a chosen function. In either case the system is screen oriented providing the user with a simple control mechanism without the need to learn another language.

## 2. DESIGN GUIDELINES

Several scholars have suggested guidelines for developing command languages. Rather than repeat their offerings we have consolidated our perceptions of the primary guidelines.

- . The system must be consistant. It must present the same environment to the user regardless of the basic system it is operating on.
- . The system must provide the user with a command sequence which is easy to use and learn, especially the most frequently used commands.
- . The system must be portable. Other machines must be able to adapt to it with minimal modification.
- . The system must provide a suitable error handling process, both in presenting error messages and in saving environments.
- . The system should be user interactive and provide the user with the option of selecting the level of prompt help he desires. Screen oriented displays are very helpful in selecting operations, but require complex interface buffering.

- . Control structures should be affluent enough to allow the user total control of the programming environment.

### 3. USER PROGRAMMING LEVELS

Different levels of user motivation and programming experience must be considered when designing a multi-purpose Command Language system. Figure 2.1 shows a rough categorization of potential users into four general programming levels.

- 
1. The Toy Store Programmer
  2. The Novice Programmer
  3. The Computer Club Programmer
  4. The Paid Programmer

Figure 2.1 Four User Programming Levels.

The first level is the "toy store" programmer. He does not really want to write an application program, but just wants to know enough language tools to run a simple game program. In general, he is in total awe of computers and makes minimal use of their actual processing capabilities.

Progressing to the second level, the first addressable command language level, we have the user who may have attended a programming course and who is now challenged to write a few simple application programs. The user at this level is enthusiastic and eager to try out his new skills. A friendly command language will motivate him to the next level. A poorly designed command language will be frustrating and quite possibly curtail future computer queries.

The third level is characterized by a quantum jump in user motivation. and usually programming skills. These

users really want to know how the internal system works and are willing to expend energy and their own time to learn varying system hardware and software configurations.

The final level is a grouping of two user factions into one entity. They are colloquially termed the learned computer scholars and the commercial programmers. They may perceive issues from different perspectives, yet their motives and knowledge of computer linguistics are compatible. Both require the full system resource capabilities at their immediate disposal in order to perform to their full potential.

Realistically, the majority of today's users and those who are of concern to a command language designer, fall within the final two categories. However, care should be taken so as not to preclude use by someone at the second level.

It is easily understood why Command Languages are so universally divergent. Designing a command language to satisfy the dynamic needs of the fourth level users while still maintaining the simplicity for the novice users is not a trivial task.

#### 4. DISPLAY FORMATS

Another issue which is receiving a great deal of attention as the state-of-the-art is the display format. Whether to display data as individual line oriented character strings or as a menu driven system. The traditional theme, driven by the hardware limitations of the past, is TTY (teletypewriter) format. i.e. Presenting a line at a time. The user responds in a similar manner by entering data in line oriented fashion. Innovations in hardware have enabled designers to break from tradition and display whole screen prompts instantaneously.

The impact of these innovations has been seen in such systems as the Xerox Smalltalk and the Apple Lisa. i. e. Incorporating the traditional command language line editing commands into onscreen menu controls. The response from critics to these nontraditional systems has been overwhelmingly positive.

The real significance of these systems is their prime objective. They strive to provide the user with a friendly interface devoid of complex, ambiguous and inconsistent command language structures. To the "real" programmers these systems appear as a threat to their mythical man over machine syndrome. Many feel that programming is an art and a science and that these systems take away their creativity by restricting how they can address the computer. They prefer to deal direct rather than through the middleman. In reality, a friendlier interface places no such restrictions. It simply makes it more understandable so that more users can address the computer directly. Until we overcome the system friendliness problem only those in the "real" programmers category will be willing and able to fully utilize the computer.

These systems still have some drawbacks such as overall cost and high memory requirements. Yet, given the history of the microprocessor, hardware designers will overcome the obstacles and make these features available to the average user.

The command languages of tomorrow will employ the ease of onscreen control with the user friendliness of multi-screen display.

### III. R&S COMMAND LANGUAGE FEATURES

#### A. RSCL COMMANDS

The RSCL commands were chosen based on the guidelines outlined in chapter two. Simplicity of use, coupled with conciseness in definition and execution were paramount in choosing the RSCL commands.

Research and practical experience indicates that many command languages are either too baroque or too simple for their intended purpose. While the RSCL does not encompass all possible programming language capabilities, it does fulfill the minimum requirements of a complete language. And, it does establish a user friendly framework, a design goal stated in chapter one.

Standard command naming conventions i.e. if-then-else, put, case etc. were adopted whenever possible. The syntax structure does not deviate from established norms, while the semantics of the command language avoids ambiguity. Exception processing and type conversion is not performed nor is it implied in any of the commands. If the system does not know what you intended, it tells you via an error message. If data types do not match across an assignment operation, the assignment is not permitted.

#### 1. BUILT IN FEATURES

Several features have been built into the RSCL which simplify both the language itself and the programs written in the language.

- . Dynamic data typing (offsets declaration requirements).
- . Both interactive and file processing capabilities.
- . Automatic file opening and closing operations performed

on both the PUT and the GET commands.

- . Format free statement entry.
- . Statements may be entered in either upper or lower case.

## 2. LANGUAGE LIMITATIONS

The language, as designed, has the following limitations:

- . Arrays and data structures are not defined.
- . Only decimal integers may be represented.
- . Floating point arithmetic is not supported.
- . Unary operators are not supported.
- . Exponentiation is not supported.

In the prototype implementation the following additional constraints were placed on the system:

- . Loop statements may not be nested.
- . Only one string variable may exist at any time.

## 3. LANGUAGE COMMANDS

The ten RSCL commands were chosen as the minimum number required to facilitate the requirements of a screen oriented command language.

The following is a brief description of each command. For a detailed description see the R&S Command Language User's Manual, Appendix B.

### a. LET command

The LET command serves as the assignment statement. The variable on the left hand side (LHS) of the "=", receives a value from the right hand side (RHS). The RHS can be either an expression, an integer, a string, or another variable (containing a value of the same data type). If the RHS is a legal arithmetic expression, its value is computed and the

result is assigned to the variable on the LHS. Otherwise, the value of the RHS is directly assigned to the variable on the LHS.

#### b. The PUT command

The PUT command consists of three parts; the device, an optional line skip parameter and the data list. It outputs newlines and the items specified in the data list to the named device.

Valid devices are: "LST", the system line printer; "CRT", the user's console screen and <FN> the name of a disk file. The device name may be followed by the word "skip" (performed only once per-command). Each occurrence causes a newline character to be output. The data list contains any combination of variables and strings (a string consists of any characters contained within double quote symbols " "). The value of the variable and the actual character string, minus the quote marks, will be output.

#### c. The GET Command

The GET command reads data from either the user's console or from files stored on the user's disk. The device name ("CRT", <FN>) precedes the receiving variables and indicates which medium the user wishes to access for his data.

#### d. IF command

The IF command is used to logically select whether or not to execute a particular set of statements. It has three components; a logical expression, a THEN set of statements and an optional ELSE set of statements. The value of the logical expression is computed. If the expression result is true, (value not equal 0), the THEN group of statements is executed. Otherwise, the ELSE group of statements is executed. If no ELSE group is included execution continues after the end of the IF statement.

e. The CASE Command

The CASE command provides for the execution of one or more statements contained within at least one sub\_case. The sub\_case is entered if it's corresponding case label matches the value of the CASE statement parameter (variable or integer). If no sub\_case label matches the label of the case value, the OTHERWISE set of statements is executed.

f. The LOOP command

The LOOP command consists of two parts; the loop iteration parameter and the body of statements. All of the statements included within the body of the loop are repeated a number of times equal to the value of the loop iteration parameter. If this value is less than or equal to 0, no statements are executed.

g. The COMMENT Command

The COMMENT command performs no actual processing. Its purpose is to allow the user to document his program and to structure it in a logically understandable form. A comment begins with a ";" and, as all other RSCL statements, it terminates with a ";". Everything contained within these two semicolons is ignored.

h. The LOCATE Command

The LOCATE Command is used to determine the current location of the cursor. It returns the row and column number.

i. The POSITION Command

The POSITION Command is used to place the cursor at a particular point (row and column position) on the screen.

#### j. The CREATE Command

The CREATE Command is used to generate a screen template. It consists of two parts; the template identifier and from 1 to 24 line definitions.

The template identifier is a variable name used to differentiate one template from another. The line definitions specify up to 80 fields per line and their associated attributes.

#### k. The DISPLAY Command

The DISPLAY Command causes a screen template and its associated data to be output to the user's console screen. It consists of two parts; the template identifier and an optional set of parameters.

The template identifier is a variable name supplied by the CREATE command when it generated the template. The parameters include a line number, a field number and text. The line and field numbers specify exactly where on the template the text has changed. These parameters are returned by the display manager whenever the data in a particular field has changed.

## IV. SYSTEM DESIGN

### A. DESIGN ASSUMPTIONS

Four major design assumptions were made early in the design phase. First, the integrated system is intended to operate on either 8 or 16 bit microcomputers.

Second, the interfaces between the host operating system, the command language and the Display Manager are all transparent to the user. The use of abstract interfaces between these three modules enables the system to be readily transportable to various microcomputers and operating systems.

Third, memory utilization was not considered a prime concern. The current trends in the state of the art towards larger, cheaper memories lead us to believe that the difference of one or two thousand bytes out of possibly one megabyte of storage is insignificant.

Fourth, processing speed was considered important, although not paramount in the design. Since the system is to be in continuous operation serving as the interface between the user and the imbedded operating system, some overhead is acceptable in exchange for the added capabilities. This overhead should occur during the user's "think" time rather than during actual processing.

### B. DESIGN CRITERIA

Several criteria were considered during the design phase. Clarity, simplicity, portability, maintenance and upward compatibility were all key factors in designing the system. The ultimate goal was to design a system that incorporated the features outlined in Chapter two in a clear and concise

manner without overburdening the user. The limited number of language commands is a direct attempt to demonstrate that a command language can be simple and can function clearly without an excessive number of nebulous commands. The sample programs listed in the users manual demonstrate the clarity of command usage.

The use of a high level system programming language, "C", serves to grant the desired portability. "C" compilers are available on many micro, mini and mainframe systems. Cross-compilers should be available for those systems which do not have a "C" compiler.

The VAX computer was used for development of the prototype system. Its processing capabilities and myriad of supporting functions along with its multiprogramming operating system and the availability of a competent support staff made it more suitable for development than a single user micro system. The use of any features unique to the VAX is purely accidental. To assure program portability, only standard "C" programming features were used. Extensions and system dependant features must be avoided in any implementation.

Program maintenance is supported by the use of a higher order programming language, functional decomposition, abstract interfaces and structured programming techniques. The utility of these factors was directly observed during the debug and test phases of the prototype implementation.

In addition, the use of a higher order language, the simplicity of the language design and the avoidance of nonstandard features ensures some degree of upward system compatibility.

### C. DESIGN DECISIONS

Three major design decisions were faced during the development of the command language. First, which language should be used to implement the system. Second, certain grammar, structure and implementation conventions had to be adopted in order to ensure system integrity. Third, the interfaces between the operating system, the Command Language module and the Display Manager module was uncertain.

"C" was chosen to implement the system because of its inherent system design features. It was originally designed as a system development tool. As such, it was felt to be the most suitable language for our purposes.

In designing the RSCL grammar, standard conventions for representing the lexical ordering and syntax of the language were devised. These conventions were documented and are included with the grammar itself in Appendix A. The use of these standards was necessary in order to assure that we both interpreted the grammar in a like way and that separate modules, which were coded independently, would operate in a like manner.

Prior to initiating the actual coding phase, several sessions were held to establish programming guidelines and intermodule interfaces. Global variables, data types, error handling, system diagnostic and integration standards were defined. Any changes or variations from these established guidelines were discussed and agreed upon before being incorporated into the respective functions. This practice proved to be invaluable during the integration and test of the prototype system. No significant interfacing problems were encountered.

The last major design decision concerned interfacing the command language interpreter (CLI) with the resident operating system and with the Display Manager program. Neither of these interfaces was built into the current system.

Instead, abstract interfaces were planned for each of these. The operating system interface will be a function call with a character string parameter. For example, to change the name of a file, a rename function would exist. This function would require two parameters; the old file name and the new file name. The file names are expected to be complete. Information such as the disk drive designator should be included in the name whether or not the user enters it. The rename function would then cause the operating system to change the name of the file in whatever ways it feels is optimal. It is transparent and irrelevant to the (CLI), whether a separate command to the operating system is generated or the data is sent to the BIOS or the disk file directory is changed. In this way, a change in the underlying operating system will require a change in only these interface functions. It makes no difference to the majority of the system whether a file name is changed by an "mv" command as in VAX UNIX, an "ren" command as in CP/M, an "r" command as in VMS, etc. The implementation of these functions is currently the topic of a separate thesis at the Naval Postgraduate School.

The interface to the Display Manager module was not implemented because it was planned to use a pre-existing program. A commercial product, called "Display Manager" is available from Digital Research. This program does all that we needed in the RSCL system. It also is capable of interfacing directly with a program written in the "C" language. Rather than devote time to development of a new program with similar capability, it was decided to purchase and use the Digital Research Display Manager. Our efforts were spent defining the display data which were of concern. This information is included in the language grammar within the "create" command. The actual commands telling the Display Manager what to display are included in the grammar within

the "display" command. Coding of these functions was postponed until the program could be purchased. At that time the actual interfacing parameters required can be determined and the functions can be written.

## V. IMPLEMENTATION

### A. DATA ORGANIZATION

The language data organization is broken up into two parts, local and global variables. Local variables are used within each function to handle internal data transactions. Data shared between two functions is passed globally. The global variables are declared in a central file, "global.interp", to maintain tight control over their assignment and use. Using global variables to transfer external data decreased the system execution time, while making the functions cleaner and easier to integrate. The design specifications clearly define each global variable, its use and what functions utilize its values.

Comments are generously dispersed throughout each function to aid the user in understanding its purpose. A header is appended to the beginning of each function, listing the other functions called and the global variables and constants used within the function.

### B. PROGRAM ORGANIZATION

Functional decomposition was used extensively throughout the program. Three separate modules comprise the fully integrated system. The O/S module is a set of functions which defines the interface to the host's operating system. These functions translate commands from the CLI to the native language of the O/S. Those commands that are not native to the host will be software emulated, if possible.

The language interpreter module has a dual function. It interfaces with both the O/S and display modules. Programs generated either interactively or by batch mode are

processed through the language interpreter. Output from the interpreter is a series of instructions to one of the other two modules.

The last link in the triad is the display module. Like the O/S module, it receives its data from the interpreter through the interface commands. The display module takes data stored in a file and transposes it onto one of the formats generated by the create command.

### C. RUNTIME ERROR CHECKING

A run time error handler is built into the system and is activated when an invalid command sequence is encountered by the interpreter. All error messages are contained in a single error function. When an error is detected the error handler is called and prints a diagnostic message and amplifying information. Depending on the severity of the error either the program is terminated or control is returned to the calling function.

## VI. SYSTEM OPERATION

The RSCL is capable of operating either in an interactive or a batch mode. For batch mode operation, programs can be written using any standard text editing program. The file containing the source code must be called "RSCL".

At execution time, the CLI determines if a file exists with the name "RSCL". If one is found, it is assumed to contain the source statements. The CLI then executes in a batch mode taking its input from the source file. Otherwise, the CLI reads its instructions from the user's console.

When operating in an interactive mode, the user must still follow the complete format of the language structure. That is, the program begins with the word "program", terminates with the word "end." and each statement terminates with a ";".

## VII. CONCLUSIONS AND RECOMMENDATIONS

The command language design and a prototype implementation, have been completed. This design is now reviewed to determine which of our original goals have been met or can be met with further work and which, if any, were not found to be feasible.

### A. GOALS

The goal of this work was to design a command language which runs on microprocessor based computer systems. The purpose of the language was to allow rapid definition of a screen oriented user interface. The language was to be simple, easy to use and readily understandable. Maintainability and portability across different machines and operating systems were prime concerns. Processing efficiency was considered, but only secondarily to the other factors.

### B. PROBLEM AREAS

The RSCL is complete and workable as designed. Known problem areas which are stated as constraints in the language are not inherent problems. They can be eliminated during future enhancements. The only area which we see as a potential problem to the system design is related to the Display Manager interface. The design in this area was purposefully made generic via the principles of abstract interfaces and information hiding. However, if the functions required by the CLI are not available, some redesign may be necessary. Because of our research in the area before creating the design, we do not feel this is a major concern. The CLI module should be easily interfaced to the other two major system modules when they become available.

### C. FUTURE WORK

In order to create a complete and deliverable product further work is required in four areas; the operating system interface routines must be completed, enhancements must be added to eliminate the constraints discussed in Chapter three, the three main system modules must be integrated, studies should be performed to determine user needs and reactions.

The operating system interface routines are already being developed under a separate thesis effort at the Naval Postgraduate School. Assuming that a copy of the Display Manager Program is obtained from Digital Research and that a "C" compiler is available for the NPS microprocessor system, the system enhancements and module integration can be accomplished under another thesis. Concurrently with the system integration, research should be performed to determine sample presentation formats. They could then be created in the RSCL.

APPENDIX A  
COMMAND LANGUAGE GRAMMAR

The convention used for describing the grammar of the command language is described in table I.

TABLE I  
Grammar Convention

SYMBOL   MEANING

|     |  |
|-----|--|
| < > | Used as delimiters for metasympols in the grammar. Anything contained within these brackets is defined later in the grammar.   |
| [ ] | Used as delimiters surrounding optional entries.   |
| ' ' | Used as delimiters surrounding literal expressions in the grammar. Anything within these symbols must appear exactly as shown. |
|     | Used as a logical OR.  |
| ::= | Interpreted as "Defined as".   |
| ( ) | Used to group expressions.   |
| **N | Used to designate a repetitive group. Where "N" is the number of repetitions.  |

Using this convention the Command Language Grammar is defined as follows:

```
PROGRAM ::= 'PROGRAM' <IDENTIFIER> <STATEMENTS> 'END.'  
STATEMENTS ::= ( <LET STATEMENT> | <IF STATEMENT>  
                | <PUT STATEMENT> | <GET STATEMENT>  
                | <LOOP STATEMENT> | <CASE STATEMENT>  
                | <COMMENT> | <DISPLAY> | <CREATE> ) ';' ;  
                [ <STATEMENTS> ]
```

```

LET_STATEMENT ::= 'LET' <IDENTIFIER> '=' ( <EXPRESSION>
                | <IDENTIFIER> | <NUMBER> | <STRING> )
IF_STATEMENT  ::= 'IF' <LOG_EXP> 'THEN' <STATEMENTS>
                [ 'ELSE' <STATEMENTS> ] 'ENDIF'
PUT_STATEMENT ::= 'PUT' <PUT_DEVICE> [ 'SKIP' ] <LIST>
PUT_DEVICE    ::= 'CRT' | 'LST' | <FNAME>
LIST          ::= ( <IDENTIFIER> | <STRING> ) [ <LIST> ]
GET_STATEMENT ::= 'GET' <GET_DEVICE> <ID_LIST>
GET_DEVICE    ::= 'CRT' | <FNAME>
ID_LIST       ::= <IDENTIFIER> [ <ID_LIST> ]
FNAME         ::= [ <CHARACTER> ':' ] <IDENTIFIER>
                [ '.' <IDENTIFIER> ]
LOOP_STATEMENT ::= 'LOOP' ( <IDENTIFIER> | <NUMBER> )
                 <STATEMENTS> 'ENDLOOP'
CASE_STATEMENT ::= 'CASE' <IDENTIFIER> ':' <CASE_NUM>
                 'OTHERWISE:' <STATEMENTS> 'ENDCASE'
CASE_NUM      ::= ( <NUMBER> | <IDENTIFIER> ) ':' <STATEMENTS>
                 [ <CASE_NUM> ]
COMMENT       ::= ';' <ANYTHING>
IDENTIFIER    ::= <CHARACTER> [ <SUB_ID> ]
SUB_ID        ::= [ '_' ] ( <CHARACTER> | <DIGIT> ) [ <SUB_ID> ]
EXPRESSION    ::= ' ( ' <TERM> [ <ARITH_OPR> <SUB_EXP> ] ' ) '
SUB_EXP       ::= <TERM> [ <ARITH_OPR> <SUB_EXP> ]
TERM          ::= <EXPRESSION> | <IDENTIFIER> | <NUMBER>
LOG_EXP       ::= ' ( ' <LOG_TERM> [ <LOG_OPR> <SUB_LOG> ] ' ) '
SUB_LOG       ::= <LOG_TERM> [ <LOG_OPR> ( <SUB_LOG>
                | <LOG_EXP> ) ]
LOG_TERM      ::= <LOG_EXP> | <IDENTIFIER> | <NUMBER>
SPACES        ::= ' ' | ' ' <SPACES>
NUMBER        ::= <DIGIT> | <DIGIT> <NUMBER>
CHARACTER     ::= 'A' | 'B' | 'C' | 'D' | 'E' | 'F' | 'G'
                | 'H' | 'I' | 'J' | 'K' | 'L' | 'M' | 'N'
                | 'O' | 'P' | 'Q' | 'R' | 'S' | 'T' | 'U'
                | 'V' | 'W' | 'X' | 'Y' | 'Z' | 'a' | 'b'
                | 'c' | 'd' | 'e' | 'f' | 'g' | 'h' | 'i'
                | 'j' | 'k' | 'l' | 'm' | 'n' | 'o' | 'p'
                | 'q' | 'r' | 's' | 't' | 'u' | 'v' | 'w'
                | 'x' | 'y' | 'z'
DIGIT         ::= '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7'
                | '8' | '9'
ARITH_OPR     ::= '+' | '-' | '*' | '/'
LOG_OPR       ::= 'EQ' | 'LT' | 'GT' | 'NE' | 'LE' | 'GE'

```

```

LOG_FUNC ::= 'AND' | 'OR' | 'NOT' | 'CON'
STRING  ::= '' <ANYTHING> ''
ANYTHING ::= ( <DIGIT> | <CHARACTER> | <ARITH_OPR>
              | <OTHERS> [ <ANYTHING> ] )
OTHERS   ::= '!' | '(' | ')' | '?' | '$' | ':' | '@' | '#' |
              '&' | '=' | '%' | '"' | '<' | '>'
DISPLAY ::= 'DISPLAY' <IDENTIFIER> [ <PARAMS> ]
PARAMS  ::= '(' [ <LINE> ] ':' [ <FIELD> ] ','
LINE     ::= NUMBER
FIELD    ::= NUMBER
TEXT     ::= ANYTHING
LOCATE   ::= 'LOCATE' <ROW> <COL>
POSITION ::= 'POSIT' <ROW> <COL>
ROW      ::= NUMBER
COL      ::= NUMBER
CREATE   ::= 'CREATE' <IDENTIFIER> <DEF_LINE> **24 'END'
DEF_LINE ::= 'DEF_LINE' <NUMBER> [ '-' <NUMBER> ]
           ( <DEF_FIELD> **80 | 'BLANK' ) 'ENDLINE' ';'
DEF_FIELD ::= 'DEF_FIELD' <IDENTIFIER> <ATTRIBUTES> ';'
ATTRIBUTES ::= '(' [ <LENGTH> ] ':' [ <VALUE> ] ':'
               [ <ACCESS> ] ':' [ <BACKGROUND> ] ':'
               [ <FOREGROUND> ] ':' [ <VIDEO> ] ':'
               [ <UNDERLINE> ] ':' [ <INTENSITY> ] ':'
               [ <TYPE> ] ')'
LENGTH   ::= NUMBER
VALUE    ::= ANYTHING
ACCESS   ::= 'R/O' | 'R/W'
FOREGROUND ::= DIGIT
BACKGROUND ::= DIGIT
VIDEO    ::= 'NORMAL' | 'INVERSE'
UNDERLINE ::= 'ON' | 'OFF'
INTENSITY ::= 'BRIGHT' | 'DIM'
TYPE     ::= 'ALPHANUM' | 'NUMBER' | 'CHAR' | 'STRING'

```

APPENDIX B  
R&S COMMAND LANGUAGE USER'S MANUAL

**A. INTRODUCTION**

The R&S Command Language (RSCL) is designed to create micro-processor shell formats from within user designed software programs. Programs written in the language will interface with the display module to output data in the specified screen format. Menus are utilized to facilitate program entry and apprise users of available formatting options. The language uses an interpreter, written in "C", to execute the programs.

**B. LEXICAL CONVENTIONS**

There are seven types of tokens: identifiers, integers, strings, arithmetic operators, logical operators, logical functions and others. In general blanks, tabs, comments and newlines are ignored except as they serve to separate tokens. At least one of these characters is required to separate otherwise adjacent identifiers. The language does not incorporate any reserved words in the grammar. Each of the RSCL statements is considered a keyword when used at the beginning of a command sequence, however, since keywords are not treated as reserved words they are allowed to be assigned as identifiers latter in a command line. The semi-colon acts as a statement terminator.

**1. TOKEN DESCRIPTIONS**

Each word is scanned for inclusion in one of the seven identified token types. The tokens are then processed one at a time through the CLI. The following subsections describe the token formats in detail.

### a. IDENTIFIERS

Identifiers may consist of alphanumeric characters and the underscore symbol. The first character must be alphabetic. It is optionally followed by characters, underscores or digits. Upper or lower case alphabetic characters are allowed but are not distinguished. The standard convention of not allowing an identifier to terminate with an underscore applies. Identifiers have a maximum length of ten characters and their value can be one of three types: character, string or integer.

#### BNF format:

```
IDENTIFIER ::= <CHARACTER> <SUB_ID>
SUB_ID ::= '_' ( <CHARACTER> | <DIGIT> ) <SUB_ID>
```

### b. NUMBERS

Numbers are formed by concatenating one or more digits onto a digit. Only digits are used to form numbers. Numbers are not re-definable data types.

#### BNF format:

```
NUMBER ::= <DIGIT> | <DIGIT> <NUMBER>
DIGIT ::= '0' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
```

### c. STRINGS

Strings are any ASCII print character(s) between double quotation marks (" "). The language reads "this is a string" as a single string.

#### BNF format:

```
STRING ::= '"' <ANYTHING> '"'
ANYTHING ::= ( <DIGIT> | <CHARACTER> |
               <ARITH_OPR> | <OTHERS> <ANYTHING>
```

#### d. ARITHMETIC OPERATORS

Standard arithmetic operators i.e. "+", "-", "\*", "/" are implemented within the language. Unary operations are not currently supported by the language.

**BNF format:**

```
ARITH_OPR ::= '+' | '-' | '*' | '/'
```

#### e. LOGICAL OPERATORS

Alphabetic type characters i.e. "EQ", "LT", "GT", "NE", "GE", "LE" are used to perform logical operations. The first three equate to equals, less than, and greater than respectively. The last three equate to not equal, greater than or equal, and less than or equal. All expressions are required to be parenthesized i.e. (A GE B) or (4 LT 9).

**BNF format:**

```
LOG_OPR ::= 'EQ' | 'LT' | 'GT' | 'NE' | 'GE' | 'LE'
```

#### f. LOGICAL FUNCTIONS

Logical functions also use alphabetic type characters i.e. "AND", "OR", "NOT", "CON" to perform their functions. The "AND", function returns true if the two arguments bracketing the "AND" are both true. The "OR" function returns true if either of the bracketing arguments is true. The "NOT" function logically complements its operand. The "CON" function concatenates a string onto another string. Like the logical operators, parentheses are required in logical expressions i.e. ((Z GE T) AND (M LT W)) where Z, T, M, and W are variables or expressions which evaluate to comparable data types.

**BNF format:**

```
LOG_FUNC ::= 'AND' | 'OR' | 'NOT' | 'CON'
```

## g. OTHERS

The others token type is a collection of the remaining standard ASCII print character types i.e. "(", ")", "&", "%", "#", etc. These characters represent their normal meaning except where their meaning is negated i.e. "GT" replaces ">" sign in the grammar convention.

### BNF format:

```
OTHERS ::= ' ' | '(' | ')' | '!' | ':' | '?' | '$' | '|' | '@' | '#' | '&' | '=' |
          '%' | '"' | ' ' | '<' | '>' | '.' | ',' | ' '
```

## C. DECLARATIONS

The language does not provide for any variable pre-declaration. New variables on the LHS or RHS, if reading in data from the CRT (screen) or a file, will be assigned the same data type as the received data automatically. Type conversions are not performed in the language.

## D. SYNTAX

The BNF (Backus Naur Form) syntax structure for the grammar is provided in Appendix A.

## E. PROGRAM STRUCTURE

All programs written in the RSCL are comprised of three parts; a header, statements to execute and a trailer. Figure B.1 shows the format of a simple program.

This sample demonstrates the overall program structure. The first line, "program sample" is the program header. Note, that it does not include a semicolon. A semicolon is a statement terminator (a semicolon is required at the end of every statement). The complete statement is "program test <executable statements> end.;"

```

program sample
  put crt skip "Enter a value for the loop count.";
  get crt a;
  loop a
    if ( a eq 2)
      then
        put crt "The value of a is " a;
      else
        get testfile.dat b;
        put crt skip "When a = 2, b = " b;
      endif;
    endloop;
  end.

```

Figure B.1 Sample Command Language Program.

The second through twelfth lines are the executable statements. They perform the actual processing. The trailer is "end.;".

The indentation and structured appearance is optional. The CLI ignores blanks and carriage returns. Therefore, multiple statements can be placed on a single line and a single statement can be split over several lines. Figure B.2 shows two legal ways to write the same statements.

Sample of combined lines.

```
let a = (b+1); put crt a;
```

Sample of line splitting.

```
let
a= ( b
+1 )
;put crt
a;
```

Figure B.2 Example of Two Line Formatting Techniques.

While no one should write a program in the second format, if the code needs to be packed, any format is acceptable so long as variable names are not split between lines. In that case they will be treated as two separate variables.

Now, knowing the general structure of an RSCL program, each of the ten individual statements are discussed in the following sections. Each statement's function and format, the constraints on its use and the error messages which can occur with their probable cause(s) are described.

### 1. The LET Statement

The LET statement is used to perform arithmetic operations and to assign values to variables. When performing arithmetic, the expression on the RHS must be contained within parenthesis. The value of that expression will then be assigned to the variable on the LHS. If no arithmetic is required, the RHS may contain either an integer, a string or a variable. In that case, either the integer value, the actual string or the value of the variable will be assigned to the variable on the LHS.

If the variable on the LHS is not defined, it is dynamically defined according to the type and value of the RHS. If the variable(s) on the RHS are not defined, an error message is printed. If both variables are defined, their types are compared to ensure that the assignment is correct.

#### a. Format

A LET statement must be in the form:

```
'let' <identifier> '=' ( <expression> | <identifier>
                        | <number> | <string> )
```

Where the word "LET" is the keyword and must be the first word in the statement. "LET" is followed by an identifier which is treated as the LHS of the statement and will be the

recipient of the assignment. Next, the equals sign, "=", is expected. This is used to separate the LHS from the RHS and to show the direction of assignment. It should not be confused with the standard relational operator "=" which means equality. ( In RSCAL equality is represented by the string "eq"). The RHS may contain only one of either an expression, an identifier, a number or a string. Upon execution of the let statement, the value of the RHS is assigned to the variable on the LHS.

The expression on the RHS may be a valid arithmetic expression containing variables and the arithmetic operators of "+", "-", "\*" and "/". These operators hold their standard meaning of addition, subtraction, multiplication and division. The precedence of operations may be either implied or explicitly declared by the use of parentheses. The implied precedence is "\*" equals "/" and "+" equals "-". While "\*" and "/" are the higher precedence and are always performed before "+" or "-". Operations of equal precedence are performed left to right. Figure B.3 illustrates the LET statement format.

#### b. Error Types

The error messages associated with the LET statement are:

**MESSAGE:**

AN IDENTIFIER was expected, but ssss was found at l111.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "l111" in the input line. Check the syntax of the statement containing this line.

**MESSAGE:**

= was expected, but ssss was found at l111.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "l111" in the input line. An "=" was expected designating the direction of the value assignment in the let statement.

**MESSAGE:**

AN ARITHMETIC EXPRESSION was expected, but ssss was found at l111.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "l111" in the input line. The RHS of the let statement did not contain a valid arithmetic expression. Most likely a matching parenthesis was omitted.

**MESSAGE:**

AN ARITHMETIC OPERATOR was expected, but ssss was found at l111.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "l111" in the input line. The RHS of the LET statement did not contain a valid arithmetic operator between two identifiers.

**MESSAGE:**

Undefined identifier, ssss at pppp in line: l111

**EXPLANATION:**

"ssss" is the token that was found prior to the point "pppp" in the input line "l111". An identifier in the RHS of the let statement did not have a value. All identifiers must be set before they can be referenced.

**MESSAGE:**

Data type mismatch. A string type was expected at pppp in line: l111

**EXPLANATION:**

The LHS of the LET statement was of type string but the RHS was not.

```
let a = 7;
```

Assigns the integer value 7 to the variable "a". If "a" is undefined it will also dynamically declare variable "a" type "I" for integer.

```
let a = b;
```

Assigns the value of "b" to the variable "a". If "b" does not have a value then an error is called. If both "a" and "b" have values then a type check is made. Otherwise, "a" is dynamically assigned the data type of "b".

```
let a = ((b + c) * 7);
```

Assigns to the variable "a" the resulting value of the RHS expression. If "a" is an undefined variable then it will dynamically receive the same data type as the expression result or if "a" is defined the LHS and RHS types are compared.

```
let a = "this is a test";
```

Assigns the string, "this is a test", to the variable "a". If "a" is undefined then it will be dynamically assigned data type "S" in the symbol table or variable "a" is compared for data type "S" string.

Figure B.3 SAMPLE LET STATEMENTS.

### c. Usage Constraints

A maximum of 20 operations may be nested in the arithmetic expression. The type checking is performed based on the type of the right-most variable in the RHS.

## 2. The GET Statement

The GET statement is used to read data into the program from some external device and assign that data value to a program variable.

### a. Format

A GET statement must be in the form:

```
'get' <device> <list>
```

Where the word "GET" is the keyword and must be the first word in the statement. "Get" is followed by a device. This device may be either "CRT" for the user's console or the name of a file. Anything which is not "CRT" is considered a file. The name of the file may optionally be prefaced by a disk drive designator and/or suffixed by a file type. The total file name follows the file naming conventions established for the CP/M operating system.

Following the device is a list of identifiers which will receive the values as read from the input device. If the identifiers are already defined, the data will be read according to the defined type. Otherwise, the identifier's type will be set depending on the type of the data which is read. Figure B.4 illustrates the GET statement format.

```
get CRT a (b,c...);
```

Reads the next terminal input and assigns it to the variable "a". If the variable "a" is undefined it will dynamically assign the input's data type to "a". Otherwise, it will perform a type check on "a". More than one input can be read from the terminal during a get statement. Type checking is done on each receiving variable.

```
get <FN> a (b,c...);
```

Opens the designated data file <FN> and reads the data in sequential order. The receiving variable(s) are either dynamically assigned the input's data type (undeclared) or a type check is performed.

Figure B.4 SAMPLE GET STATEMENTS.

## b. Error Types

The error messages associated with the GET statement are:

### MESSAGE:

DEVICE 'CRT' or a file name was expected, but ssss was found at llll.

### EXPLANATION:

"ssss" is the token that was found prior to the point "llll" in the input line. The word 'get' must be followed by the name of the device from which to read the data.

### MESSAGE:

Filename -- (<FN> [.<FT>]) -- was expected, but ssss was found at llll.

### EXPLANATION:

"ssss" is the token that was found prior to the point "llll" in the input line. A file name may be up to 8 characters long and optionally prefaced by a drive designator (one character followed by a colon).

Filetype -- (<FN> [.<FT>]) -- was expected, but ssss was found at llll.

### EXPLANATION:

"ssss" is the token that was found prior to the point "llll" in the input line. A file type may be up to 3 characters long and must be prefaced by a period. A file type only appears after a valid file name.

### MESSAGE:

Unable to open file - check <FN> is capitalized

### EXPLANATION:

The file designated in the GET statement does not exist. Check the spelling of the file name. Be sure to watch for discrepancies in capitalization.

**MESSAGE:**

Cannot read from the list device at pppp in  
line: 1111

**EXPLANATION:**

"pppp" is the point in the input line "1111" at  
which the error occurred. A device type of "LST" is illegal  
for the GET statement.

c. Usage Constraints

There are no usage constraints in the GET statement.

3. The PUT Statement

The PUT statement is used to output data from a program vari-  
able to some external device.

a. Format

A PUT statement must be in the form:

```
'put' <device> ['skip'] <list>
```

Where the word "PUT" is the keyword and must be the first  
word in the statement. "PUT" is followed by a device. This  
device may be either "CRT" for the user's console, "LST" for  
the line printer or the name of a file. Anything which is  
not "CRT" or "LST" is considered a file. The name of the  
file may optionally be prefaced by a disk drive designator  
and/or suffixed by a file type. The total file name follows  
the file naming conventions established for the CP/M oper-  
ating system.

The device is optionally followed by the word  
'skip'. If included, this will cause a newline control code  
to be transmitted to the output device. Note, the skip is  
only done once per statement.

Next is a list of identifiers and/or character  
strings. Figure B.5 illustrates the PUT statement format.

```
put CRT a (b,c...);
```

Displays on the CRT (screen) the value of the variable "a". Multiple displays (b,c...) are allowed.

```
put CRT SKIP (a,b...);
```

Skips a line prior to displaying the variable data. The skip is performed only once prior to displaying the variable(s) value(s).

```
put LST a (b,c...);
```

Toggles the printer on (providing it is turned on) and transfers the variable(s) value(s) to it.

```
put LST <FN>;
```

Toggles the printer on (providing it is turned on) and transfers the data contained in the designated file <FN>.

```
put <FN> a (b,c...);
```

Opens the designated file <FN> and stores the variable(s) value in the file. The file <FN> is automatically closed upon statement termination.

**Figure B.5 SAMPLE PUT STATEMENTS.**

#### b. Error Types

The error messages associated with the PUT statement are:

**MESSAGE:**

DEVICE "CRT" or "LST" or a file name was expected, but ssss was found at llll.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "llll" in the input line. The word 'put' must be followed by the name of the device on which the data is to be written.

**MESSAGE:**

Filename -- (<FN> [.<FT>]) -- was expected, but ssss was found at llll.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "l111" in the input line. A file name may be up to 8 characters long and optionally prefaced by a drive designator (one letter followed by a colon).

**MESSAGE:**

Filetype -- (<PN> [.<FT>]) -- was expected, but ssss was found at l111.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "l111" in the input line. A file type may be up to 3 characters long and must be prefaced by a period. A file type only appears after a valid file name.

**MESSAGE:**

Undefined identifier, ssss at pppp in line: l111

**EXPLANATION:**

"ssss" is the token that was found prior to the point "pppp" in the input line "l111". A value must be defined for any variable before it can be output. Be sure that all designated variables are set to some value before they are referenced.

### c. Usage Constraints

If the data is being put to a file, that file is opened in append mode. Therefore, if a new file is desired, the user must ensure that any previous file with that name is erased prior to executing the PUT statement.

## 4. The IF Statement

The IF statement executes a set of statements based on the logical value of the IF clause. If this value is true (not 0), the THEN group of statements is executed. If the IF clause value is false (0), the ELSE group of statements is executed. The ELSE group is optional. If it does not exist

and the IF clause value is false, the entire IF statement is ignored.

a. Format

An IF statement must be of the form:

```
'if' <logical expression> 'then' <statements>
```

Where the word "IF" is the keyword and must be the first word in the statement. "IF" is followed by a logical expression. This expression must be contained within parentheses and may be any valid combination of logical operators (eq, lt, gt, ne, le, ge), logical functions (and, or, not) variables and numbers. Precedence of operations is determined solely on the bases of parenthetical grouping.

The logical expression must be followed by the word "THEN" and the group of statements which will be executed if the logical expression is true. This group of statements terminates either with the word "ELSE" or the word "ENDIF".

If the logical expression is false, the THEN group of statements is skipped and the ELSE group is executed (if it exists). The IF statement terminates upon detection of the word "ENDIF;". Figure B.6, illustrates the IF statement format.

b. Error Types

The error messages associated with the IF statement are:

**MESSAGE:**

```
An IF statement must have a logical expression  
at pppp in line: llll
```

**EXPLANATION:**

"pppp" is the point in the input line "llll" at which a logical expression was expected. Check for matching parentheses.

```
if <logical expression> then
  <statements>
else
  <statements>
endif;
```

The logical expression portion is tested first. If true, the statements in the THEN portion (any RSCL statements) are executed in order. The statements contained in the ELSE (optional) portion are executed only when the IF condition returns false. The IF statement is terminated by an ENDIF.

Figure B.6 SAMPLE IF STATEMENT.

**MESSAGE:**

THEN was expected but ssss was found at llll.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "pppp". The THEN clause is mandatory in an IF statement. Be sure that all designated variables are set before they are referenced.

**MESSAGE:**

ENDIF was expected but ssss was found at llll.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "pppp". An IF statement must terminate with the word "ENDIF".

c. Usage Constraints

There are no usage constraints for an IF statement.

5. The LOOP Statement

The LOOP statement repeats a set of statements a specified number of times. Any number of repetitions may be specified via either a number constant or a variable entry.

a. Format

A LOOP statement must be in the form:

```
'loop' ( <identifier> | <number> ) <statements> 'endloop;'
```

Where the word "LOOP" is the keyword and must be the first word in the statement. "LOOP" is followed by either a number or an identifier which gives the number of times the loop is to be executed. The loop checks this value before execution. If the loop value is  $\leq 0$ , the statements in the loop are skipped. Otherwise, the inner statements are repeated until the loop counter reaches 0. The loop counter cannot be changed once the loop has begun executing. Even if the identifier used for the loop counter is altered, the loop will not be affected. Figure B.7 illustrates the LOOP statement format.

```
loop a
  <statements>
endloop;
```

The variable "a" contains the number of iterations that the statements contained within the loop will be executed. Any combination of valid RSCL statements is allowed.

```
loop 7
  <statements>
endloop;
```

The only difference in this statement is the loop counter is in integer form vice identifier form. The loop execution sequence is not altered.

Figure B.7 SAMPLE LOOP STATEMENT.

## b. Error Types

The error messages associated with the LOOP statement are:

### MESSAGE:

Undefined identifier, ssss at pppp in line: llll

### EXPLANATION:

"ssss" is the token that was found prior to the point "pppp" in the input line "llll". A value must be defined for any variable before it can be used as a loop counter. Be sure that all designated variables are set before they are referenced.

### MESSAGE:

An integer or variable loop count was expected but ssss was found at llll

### EXPLANATION:

"ssss" is the token that was found prior to the point "llll". A loop counter can only be an integer or an identifier.

## c. Usage Constraints

Nested loops cannot be used.

## 6. The CASE Statement

The CASE statement executes a set of statements based upon the case variable. If one of the cases matches the value of the case variable then that set of statements is executed. If none match, then the OTHERWISE set of statements is executed.

### a. Format

The CASE statement must be in the form:

```
'case' <identifier> ':' case_num  
      'otherwise:' <statements> 'endcase'
```

Where the word "CASE" is the keyword and must be the first word in the statement. "Case" is followed by an identifier and a colon. This is the case variable. Each of the cases that follow begin with either a number or an identifier followed by a colon. This value is compared with the value of the case variable. If they are equal, then all the statements in the case element (up to the next case number) are executed. If no case number matches the case variable then the statements in the otherwise clause are executed. The CASE statement is terminated with the word "ENDCASE" and a semicolon. Figure B.8 illustrates the CASE statement format.

```
case a:  
  b: <statements>  
  c: <statements>  
  6: <statements>  
  otherwise  
endcase;
```

The case statement uses a variable or an integer to indicate which case element will be invoked. The "a" represents the data type of the case element index. If none of the case elements are invoked then the otherwise case element is executed. Any valid RSCL statement is allowed.

Figure B.8 SAMPLE CASE STATEMENT.

#### b. Error Types

The error messages associated with the CASE statement are:

**MESSAGE:**

Undefined identifier, ssss at pppp in line: 1111

**EXPLANATION:**

"ssss" is the token that was found prior to the point "pppp" in the input line "1111". A value must be

defined for any variable before it can be used as a loop counter. Be sure that all designated variables are set before they are referenced.

**MESSAGE:**

-- : -- was expected but ssss was found at pppp.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "pppp". A case variable must be followed by a colon.

**MESSAGE:**

OTHERWISE was expected but ssss was found at pppp.

**EXPLANATION:**

"ssss" is the token that was found prior to the point "pppp". A CASE statement must include an OTHERWISE clause to handle the event when no labeled case value was matched.

c. Usage Constraints

There are no usage constraints for the case statements.

7. The CREATE Statement

The create function was not coded because the interface between the CLI and display modules is unknown. The create module was designed to interface with a commercial product. The product is still enroute to the school. When coded the create module will assign attribute values to specified fields. The resulting template is then utilized for data display through the display module.

8. The DISPLAY Statement

The display function was intended to be an external commercial product purchased from a local vendor. Unfortunately, the supply system was uncooperative and the product never arrived. As designed, display manager takes the output data

and transposes it onto the requested screen shell created in the create module.

#### F. GENERAL ERROR HANDLING

The system and syntax error handler messages are formatted as follows:

```
      ("**** SYNTAX or SYSTEM ERROR ****")
              (ERROR MESSAGE(S))
```

##### MESSAGE:

Symbol table exceeded.

##### EXPLANATION:

The maximum length of the symbol table was exceeded, too many variables in the program.

##### MESSAGES:

Premature end of input encountered.

##### EXPLANATION:

The program ended without a proper terminator i.e. END. Program could be in the middle of a command when the input terminates.

##### MESSAGES:

Unrecognized character, ssss in line: llll.

##### EXPLANATION:

"ssss", a non ASCII type token, was encountered prior to the point "llll" in the input line.

##### MESSAGES:

String length exceeds (132) in line llll

##### EXPLANATION:

The token prior to the point "llll" in the input line exceeds the maximum string length of (132).

##### MESSAGES:

PROGRAM was expected, but ssss was found at llll.

**EXPLANATION:**

Program's must start with the constant "PROGRAM" followed by the program name.

**MESSAGES:**

AN IDENTIFIER was expected, but ssss was found at line 1111.

**EXPLANATION:**

This could have several meanings. LHS's of let statements require an identifier (variable). Data file reads also require a variable to receive transferred data.

**MESSAGES:**

END. was expected, but ssss was found at line 1111.

**EXPLANATION:**

An input following a statement must be either another statement or an (END.).

**MESSAGES:**

No legal Command Language statement was found prior to the point 1111 in the input line.

**EXPLANATIONS:**

This error message is only invoked during the first statement following the program name.

**MESSAGES:**

expected at ssss in line 1111.

**EXPLANATION:**

Semicolons terminate all statements. Check the statement at the indicated line.
